Abstract

We consider an exact $\mu-\tau$ reflection symmetry in neutrino sector realized at the GUT scale in the context of the seesaw model with and without supersymmetry. Assuming the two lighter heavy Majorana neutrinos are degenerate at the GUT scale, it is shown that the renormalization group (RG) evolution from the GUT scale to the seesaw scale gives rise to breaking of the $\mu-\tau$ symmetry and a tiny splitting between two degenerate heavy Majorana neutrino masses as well as small variations of the CP phases in Y_ν, which are essential to achieve a successful leptogenesis. Such small RG effects lead to tiny deviations of θ_{23} from the maximal value and the CP phase $\delta_{\rm CP}$ from $\frac{\pi}{2}$ imposed at the GUT scale due to $\mu-\tau$ reflection symmetry. In our scenario, the required amount of the baryon asymmetry η_B can be generated via so-called resonant e-leptogenesis, in which the wash-out factor concerned with electron flavor plays a crucial role in reproducing a successful leptogenesis. We show that CP violation responsible for the generation of baryon asymmetry of our universe can be directly linked with CP violation measurable through neutrino oscillation as well as neutrino mixing angles θ_{12} and θ_{13}. We expect that, in addition to the reactor and long baseline neutrino experiments, the measurements for the supersymmetric parameter $\tan\beta$ at future collider experiments would serve as an indirect test of our scenario of baryogenesis based on the $\mu-\tau$ reflection symmetry.

I. INTRODUCTION

The present neutrino experimental data [1, 2, 3] exhibit that the atmospheric neutrino deficit points toward a maximal mixing between the tau and muon neutrinos, however, the solar neutrino deficit favors a not-so-maximal mixing between the electron and muon neutrinos, *i.e.*, $|U_{\mu 3}| \simeq |U_{\tau 3}| \simeq 1/\sqrt{2}$, where U is the leptonic PMNS mixing matrix. In addition, although we do not have yet any firm evidence for the neutrino oscillation arisen from the 1st and 3rd generation flavor mixing, there is a bound on the mixing element U_{e3} from CHOOZ reactor experiment, $|U_{e3}| < 0.2$ [4]. Although neutrinos have gradually revealed their properties in various experiments since the historic Super-Kamiokande confirmation of neutrino oscillations [1], properties related to the leptonic CP violation are completely unknown yet. CP violations in the leptonic sector are also obligatory, if the matter and antimatter asymmetry of the Universe is made through leptogenesis scenario [5] in the seesaw models [6].

Recently, the so-called μ-τ reflection symmetry [7, 8] has been imposed in light neutrino mass matrices so that the maximal atmospheric mixing $\theta_{23} = \pi/4$ as well as the maximal value for the Dirac CP violating phase $\delta_{\mathrm{CP}} = \pi/2$ are predicted [9, 10]. Under the μ-τ reflection symmetry in the context of a seesaw model, it is supposed that the right-handed neutrinos transform into the charge conjugates of themselves, $N_i \rightarrow N_i^c$ and the light left-handed neutrinos into $\nu_e \rightarrow \xi_1 \nu_e^c, \nu_\mu \rightarrow \xi_2 \nu_\tau^c, \nu_\tau \rightarrow \xi_2 \nu_\mu^c$ [7, 8, 11] with the corresponding phases ξ_i. The effective mass matrix derived from the seesaw mechanism is invariant under the $\mu - \tau$ reflection symmetry, too. In the light of the CP violation from the neutrino oscillations [12], the $\mu - \tau$ reflection symmetry indicates that, for given values of mixing angles, the CP asymmetry $P(\nu_\mu \rightarrow \nu_e) - P(\bar{\nu}_\mu \rightarrow \bar{\nu}_e)$ is maximal.

In this paper, we consider a seesaw model with the $\mu - \tau$ reflection symmetry. In contrast with other models concerned with the $\mu - \tau$ reflection symmetry, we impose the exact symmetry at the GUT scale and consider renormalization group (RG) evolution [13, 14, 15, 16] on the neutrino Dirac Yukawa couplings, heavy Majorana neutrino masses and CP phases by running from the GUT scale to a seesaw scale. One of interesting issues concerned with neutrino models with the $\mu - \tau$ reflection symmetry is if baryogenesis can be successfully realized through leptogenesis or not. In fact, high energy cosmological CP violation responsible for baryogenesis vanishes as long as the $\mu - \tau$ reflection symmetry is kept exact and flavor effects associated with the charged leptons are not taken into account [8]. However, it has been shown that flavor effects can lead to a successful leptogenesis for $M_1 < 10^{13}$ GeV in the limit of the $\mu-\tau$ reflection symmetry as long as a partial lepton asymmetry associated with a lepton flavor does not vanish even if total lepton asymmetry is zero [11]. According to our numerical estimates made in this paper, it is not true in some cases of heavy Majorana neutrino mass spectrum with hierarchy structures like $M_1 \ll M_2 < M_3$ and $M_1 \simeq M_2 << M_3$. In such cases, as will be shown later, breaking of the $\mu-\tau$ reflection symmetry can lead to successful leptogenesis. Instead of introducing *ad-hoc* soft symmetry breaking terms, in this paper, we consider a possibility that RG evolutions of neutrino parameters can beak the $\mu-\tau$ reflection symmetry and then examine if such breaking effects due to the RG evolutions can lead to successful baryogenesis. To do that, we simply assume that two lighter heavy Majorana neutrino masses are exactly degenerate at the GUT scale. If a mass splitting between two degenerate heavy Majorana neutrinos due to the RG evolution comes out to be small, we expect that the lepton asymmetry can be resonantly enhanced [17]. However, we show that even though the total lepton asymmetry can be resonantly enhanced, the magnitude of the total lepton asymmetry is not enough to achieve successful baryogenesis in the context of the Standard Model (SM) with the $\mu-\tau$ reflection symmetry broken by RG corrections.

In general, the absolute magnitudes of the lepton asymmetries for each lepton flavor can be larger than that of the total lepton asymmetry. Furthermore, since the interactions mediated by the tau and muon coupling are in thermal equilibrium at below the temperature $M \sim 10^9$ GeV, the processes which wash out lepton number are flavor dependent and thus the lepton asymmetries for each flavor should be treated separately with different wash-out factors. It has been known that flavor effects can enlarge the area of parameter space where leptogenesis can work. Thus, it is meaningful to investigate if leptogenesis including flavor effects can be successfully realized in the case that leptogenesis without flavor effects does not work successfully. In this paper, we shall examine if the flavor effects on leptogenesis can help to achieve successful baryogenesis in the context of the SM with the $\mu-\tau$ reflection symmetry broken by RG corrections. In particular, we shall carefully discuss how the wash-out factors for each lepton flavor can be significant to achieve successful leptogenesis.

In the supersymmetric seesaw model (SSM), the baryon asymmetry of our universe can be achieved leptogenesis via the decays of heavy Majorana neutrinos. One of interesting points is that the lepton asymmetry in the SSM can be enhanced in the case of large $\tan\beta$ because it is proportional to the charged lepton Yukawa couplings $Y_l = Y_{l_{\rm SM}}(1+\tan\beta)$. Thus, even for the parameter space where leptogenesis in the SM does not work, supersymmetry can make leptogenesis working. We also expect that since the RG evolutions in the SSM are different from those in the SM, the parameter space where leptogenesis can work must be different each other. In this paper, we shall study how the results concerned with leptogenesis in the SM can change when we supersymmetrize it.

This paper is organized as follows: In Sec. II, we present a seesaw model reflecting $\mu-\tau$ reflecting symmetry at the GUT scale in the context of both SM and SSM. In Sec. III, we discuss how we can obtain a RG-improved neutrino mass matrix. We show that the RG evolutions break the $\mu-\tau$ reflection symmetry and derive the deviations of low energy neutrino mixing angles and CP phase from their tree level values which can be parameterized in terms of a parameter concerned with the RG evolution. The discussion for RG evolution from the GUT scale to low scale and useful formulae are given in Appendix. In Sec. IV, we show how successful leptogenesis can be radiatively induced in our scheme. Here, we discuss how lepton flavor effects are important to achieve successful leptogenesis and carefully estimate the wash-out factors by taking flavor effects into account. Numerical results and conclusion are given in Sec. V.

II. SEESAW MODEL WITH THE $\mu-\tau$ REFLECTION SYMMETRY

A. In case of the SM

To begin with, let us consider the Lagrangian of the lepton sector from which the seesaw mechanism works,

$$\mathcal{L}_m = -\overline{L}\mathbf{Y}_\nu N\tilde{\phi} - \overline{L}\mathbf{Y}_l l_R \phi - \frac{1}{2}\overline{N}^c \mathbf{M}_R N + h.c., \tag{1}$$

where the family indices have been omitted and $L_i,\ l_R,\ \phi,\ N,\ i=e,\mu,\tau$ stand for SU(2) lepton doublet fields, charged lepton singlet fields and Higgs scalar and singlet heavy Majorana neutrino, respectively. In the above lagrangian, $\mathbf{M}_R$, $\mathbf{Y}_l$ and $\mathbf{Y}_\nu$ are the 3×3 heavy Majorana neutrino mass matrix, charged lepton and neutrino Dirac Yukawa matrices, respectively. After spontaneous electroweak symmetry breaking, the seesaw mechanism leads to the following effective light neutrino mass term,

$$m_{\text{eff}} = -\mathbf{Y}_\nu^T \mathbf{M}_R^{-1} \mathbf{Y}_\nu \upsilon^2 \ , \tag{2}$$

where υ is a vacuum expectation value of the Higgs field with $\upsilon \approx 174$ GeV.

Let us impose the $\mu - \tau$ reflection symmetry for the neutrino sectors at the GUT scale, which is the combined operation of $\mu - \tau$ flavor exchange in PMNS mixing matrix and CP transformation on the leptonic sector [7], in the basis where both the charged lepton mass and heavy Majorana mass matrices are diagonal. Under the $\mu - \tau$ reflection symmetry, the right-handed neutrinos transform into the charge conjugates of themselves, $N_i \rightarrow N_i^c$ and thus the elements of $\mathbf{M}_R$ should be real. Then, the neutrino Dirac Yukawa matrix and the heavy Majorana neutrino mass matrix, at the GUT scale, are taken to be

$$\mathbf{Y}_\nu = \begin{pmatrix} a_1 & b_1 e^{i\phi_1} & b_1 e^{-i\phi_1} \\ a_2 & b_2 e^{i\phi_2} & b_2 e^{-i\phi_2} \\ a_3 & b_3 e^{i\phi_3} & b_3 e^{-i\phi_3} \end{pmatrix} , \qquad \mathbf{M}_R = \begin{pmatrix} M_1 & 0 & 0 \\ 0 & M_2 & 0 \\ 0 & 0 & M_3 \end{pmatrix} , \tag{3}$$

where a_i, b_i $(i = 1, 2, 3)$ of the neutrino Dirac Yukawa matrix are all real. We assume that the two heavy Majorana neutrinos are exactly degenerate in mass, which is much smaller than that of the right-handed neutrino N_3, *i.e.* $M_1 = M_2 \equiv M \ll M_3$. It turns out, after our analysis, that in the light of seesaw mechanism with such a hierarchy of heavy Majorana neutrinos the effects of the parameters a_3 and ϕ_3 on low energy neutrino phenomenology and even leptogenesis are negligibly small. Thus, for our convenience, we take $a_3 = 0$ and $\phi_3 = 0$ at the GUT scale.

Introducing several parameters defined by the ratios among the parameters appeared in Eq. (3), as follows,

$$m_0 \equiv \upsilon^2 \frac{b_3^2}{M} \ , \quad \lambda \equiv \frac{a_1}{b_3} \ , \quad \omega \equiv \frac{b_1}{b_3} \ , \quad \chi \equiv \frac{a_2}{b_3} \ , \quad \kappa \equiv \frac{b_2}{b_3} \ , \quad \eta \equiv \frac{M_3}{M} \ , \tag{4}$$

the effective light neutrino mass matrix generated through seesaw mechanism can be written as

$$m_{\text{eff}} = m_0 \begin{pmatrix} m_{ee} & m_{e\mu} & m_{e\mu}^* \\ m_{e\mu} & m_{\mu\mu} & m_{\mu\tau} \\ m_{e\mu}^* & m_{\mu\tau} & m_{\mu\mu}^* \end{pmatrix} , \tag{5}$$

where

$$\begin{aligned} m_{ee} &= \lambda^2+\chi^2 \ , \qquad\qquad\qquad\quad m_{e\mu}=\lambda\omega e^{i\phi_1}+\chi\kappa e^{i\phi_2} \\ m_{\mu\mu} &= \omega^2 e^{2i\phi_1}+\kappa^2 e^{2i\phi_2}+\frac{1}{\eta} \ , \qquad m_{\mu\tau}=\omega^2+\kappa^2+\frac{1}{\eta} \ . \end{aligned}$$

We see that the effective neutrino mass matrix $m_{\rm eff}$ reflects the $\mu-\tau$ reflection symmetry [7]. Here, we have not yet considered RG corrections to $m_{\rm eff}$ from the GUT scale to a seesaw scale, so the form of $m_{\rm eff}$ given in Eq. (5) is regarded at tree level.

It is not difficult to see that the seesaw model based on Eq. (3) leads to the normal hierarchical light neutrino mass spectrum because we take diagonal form of heavy Majorana neutrino mass matrix [18, 19, 20]. Thus, the RG effects from a seesaw scale to electroweak scale on $m_{\rm eff}$ as well as on the neutrino mixing matrix $U_{\rm PMNS}$ are expected to be very small. Starting from the $\mu-\tau$ reflection symmetric forms of Y_ν and M_R, we shall show that the $\mu-\tau$ reflection symmetry is broken due to the RG running effects between the GUT and a seesaw scale and they can lead to successful leptogenesis without being in conflict with experimental low energy constraints.

Concerned with CP violation, we notice from Eq. (5) that the CP phases $\phi_{1,2}$ coming from $\mathbf{Y}_\nu$ take part in low-energy CP violation. To see how the CP phases $\phi_{1,2}$ are correlated with low energy CP violation measurable through neutrino oscillations, let us consider CP violation parameter defined through Jarlskog invariant [21]

$$J_{\rm CP} = \frac{1}{8}\sin 2\theta_{12}\sin 2\theta_{23}\sin 2\theta_{13}\cos\theta_{13}\sin\delta_{\rm CP}=\frac{{\rm Im}[h_{e\mu}h_{\mu\tau}h_{\tau e}]}{\Delta m^2_{21}\Delta m^2_{31}\Delta m^2_{32}}, \tag{6}$$

where $h=m^\dagger_{\rm eff}m_{\rm eff}$ and $\Delta m^2_{ij}=m^2_i-m^2_j$. From the matrix given in Eq. (5) it can be written as

$$J_{\rm CP}\sim {\rm Im}[h_{e\mu}h_{\mu\tau}h_{\tau e}]\simeq m_0^6 A\kappa\omega\sin\Delta\phi_{12}+O(\eta^{-1}), \tag{7}$$

where A is the lengthy function composed of the parameters $\kappa,\omega,\chi,\lambda,\cos\Delta\phi_{12}$ and $\Delta\phi_{ij}=\phi_i-\phi_j$. We see from the above equation that $J_{\rm CP}$ is correlated with high energy CP parameter $\Delta\phi_{12}$. As long as $\Delta\phi_{12}\neq 0$ and $A\neq 0$, $J_{\rm CP}$ have non-vanishing value, which would be a signal of CP violation.

The combination of Dirac neutrino Yukawa matrices, which is relevant for leptogenesis, is given by

$$\mathbf{Y}_\nu \mathbf{Y}_\nu^\dagger = H \; = \; b_3^2 \begin{pmatrix} \lambda^2 + 2\omega^2 & \lambda\chi + 2\omega\kappa\cos\Delta\phi_{12} & 2\omega\cos\Delta\phi_{13} \\ \lambda\chi + 2\omega\kappa\cos\Delta\phi_{12} & \chi^2 + 2\kappa^2 & 2\kappa\cos\Delta\phi_{23} \\ 2\omega\cos\Delta\phi_{13} & 2\kappa\cos\Delta\phi_{23} & 2 \end{pmatrix} . \tag{8}$$

From this, we find that the hermitian quantity $\mathbf{Y}_\nu \mathbf{Y}_\nu^\dagger$ in the limit of the $\mu - \tau$ reflection symmetry leads to $\mathrm{Im}[\mathbf{Y}_\nu \mathbf{Y}_\nu^\dagger] = 0$ and thus vanishing lepton asymmetry which is undesirable for a successful leptogenesis. To generate non-vanishing lepton asymmetry, both the mass degeneracy of the 1st and 2nd heavy Majorana neutrinos and the $\mu - \tau$ reflection symmetric texture of $\mathbf{Y}_\nu$ in Eq. (3) should be broken.

B. In case of the SSM

In the SSM, the leptonic superpotential is given by

$$W_{\rm lepton} = \hat{l}_L^c \mathbf{Y}_l \hat{L} \cdot \hat{H}_d + \hat{N}_L^c \mathbf{Y}_\nu \hat{L} \cdot \hat{H}_u - \frac{1}{2} \hat{N}_L^{cT} \mathbf{M}_R \hat{N}_L^c \ , \tag{9}$$

where the family indices have been omitted and $\hat{L}$ stands for the chiral super-multiplets of the $\mathrm{SU}(2)_L$ doublet lepton fields, $\hat{H}_{u,d}$ are the Higgs doublet fields with hypercharge $\pm 1/2$, $\hat{N}_L^c$ and $\hat{l}_L^c$ are the super-multiplet of the $\mathrm{SU}(2)_L$ singlet neutrino and charged lepton field, respectively. After spontaneous electroweak symmetry breaking, the seesaw mechanism leads to a following effective light neutrino mass term,

$$m_{\rm eff} = \mathbf{Y}_\nu^T \mathbf{M}_R^{-1} \mathbf{Y}_\nu \langle H_u \rangle^2 \ , \tag{10}$$

where $\langle H_u \rangle^2 = v^2 \sin^2\beta$. For our purpose, we take the forms of $\mathbf{Y}_\nu$ and $\mathbf{M}_R$ in the SSM to be the same forms given in Eq. (5).

III. RG IMPROVED EFFECTIVE NEUTRINO MASS MATRIX

Considering the RG effects in Y_ν and M_R, we obtain a RG improved effective neutrino mass matrix via the seesaw reconstruction at the decoupling scales of the heavy neutrino singlets. The effective mass matrix at low energies can be found by running $m_{\rm eff}(Q)$ from the decoupling scales to the electroweak scale m_Z. The procedures of the RG running and the useful formulae are given in Appendix. However, in the case of the normal hierarchical neutrino mass spectrum of light neutrinos, the RG running effects from the decoupling scales of heavy Majorana neutrinos to the electroweak scale are turned out to be negligibly small. Ignoring the RG running effects from seesaw scale to the electroweak scale in Eqs. (A20,A21), we can obtain the RG improved effective neutrino mass matrix at low energy presented as follows,

$$m_{\rm eff} \simeq m_0 \begin{pmatrix} m_{ee} & m_{e\mu} & m^*_{e\mu}(1+\tilde{a}) \\ m_{e\mu} & m_{\mu\mu} & m_{\mu\tau}(1+\tilde{a}) \\ m^*_{e\mu}(1+\tilde{a}) & m_{\mu\tau}(1+\tilde{a}) & m^*_{\mu\mu}(1+2\tilde{a}) \end{pmatrix} + \mathcal{O}(y_\tau^4), \tag{11}$$

where the parameter $\tilde{a}$ corresponding to the RG correction is given as

$$\tilde{a} = \begin{cases} -\frac{3}{2}y_\tau^2 \cdot t, & \text{for SM,} \\ y_\tau^2 \cdot t, & \text{for SSM.} \end{cases} \tag{12}$$

We recast Eq. (11) with the transformation $\nu_\mu \to e^{-i\frac{\Psi}{2}}\nu_\mu$ and $\nu_\tau \to e^{i\frac{\Psi}{2}}\nu_\tau$, as [1]

$$m_{\rm eff} \simeq m_0 \begin{pmatrix} m_{ee} & \delta_{e\mu}e^{i\Phi} & \delta_{e\mu}e^{-i\Phi}(1+\tilde{a}) \\ \delta_{e\mu}e^{i\Phi} & \delta_{\mu\mu} & m_{\mu\tau}(1+\tilde{a}) \\ \delta_{e\mu}e^{-i\Phi}(1+\tilde{a}) & m_{\mu\tau}(1+\tilde{a}) & \delta_{\mu\mu}(1+2\tilde{a}) \end{pmatrix} + \mathcal{O}(y_\tau^4), \tag{13}$$

where $\Phi \equiv \Omega - \frac{\Psi}{2}$ and

$$\begin{aligned} \delta_{e\mu} &= \sqrt{\lambda^2\omega^2 + \kappa^2\chi^2 + 2\lambda\chi\kappa\omega\cos\Delta\phi_{12}}, \qquad \cos\Omega = \frac{\lambda\omega\cos\phi_1 + \kappa\chi\cos\phi_2}{\sqrt{\lambda^2\omega^2 + \kappa^2\chi^2 + 2\lambda\chi\kappa\omega\cos\Delta\phi_{12}}}, \\ \delta_{\mu\mu} &\simeq \sqrt{\kappa^4 + \omega^4 + 2\kappa^2\omega^2\cos 2\Delta\phi_{12}} + \mathcal{O}(\frac{1}{\eta}), \quad \cos\Psi \simeq \frac{\omega^2\cos 2\phi_1 + \kappa^2\cos 2\phi_2}{\sqrt{\kappa^4 + \omega^4 + 2\kappa^2\omega^2\cos 2\Delta\phi_{12}}} + \mathcal{O}(\frac{1}{\eta}). \end{aligned}$$

It is quite interesting to notice that the size of $\tilde{a}$ is very small, which breaks the $\mu - \tau$ reflection symmetry slightly in the mass matrix $m_{\rm eff}$, however, this tiny breaking effects can play a crucial role in linking between low energy neutrino data and leptogenesis, as will be shown later. This neutrino mass matrix is diagonalized by the PMNS mixing matrix $U_{\rm PMNS}$, $U^T_{\rm PMNS}m_{\rm eff}U_{\rm PMNS} = {\rm Diag}[m_1, m_2, m_3]$, where m_i $(i = 1, 2, 3)$ indicates the mass eigenvalues of light Majorana neutrinos. As a result of the RG effects, CP violation phase $\delta_{\rm CP}$ is shifted by a tiny amount, Δ_δ:

$$\delta_{\rm CP} - \frac{\pi}{2} \equiv \Delta_\delta \simeq -\tilde{a}\frac{\kappa^2 + \omega^2}{\chi^2 + \lambda^2}\frac{\cos\Phi}{\sin\Phi} \ . \tag{14}$$

---

[1] This effective mass matrix is similar to that of Ref. [18].

Here if the exact $\mu-\tau$ reflection symmetry is recovered, then $\tilde{a}\rightarrow 0$ and Δ_δ goes to zero. Atmospheric mixing angle θ_{23} is also deviated from $\pi/4$ due to the RG corrections, and the shift is approximately written by

$$\theta_{23}-\frac{\pi}{4}\simeq -2\tilde{a}\frac{\kappa^2+\omega^2}{\lambda^2+\chi^2}\simeq 2\Delta_\delta\tan\Phi\ . \tag{15}$$

The magnitude of the unknown angle θ_{13}, which will complete our knowledge of neutrino mixing, can be written as

$$\tan 2\theta_{13}\simeq\frac{\sqrt{2}(\kappa\chi+\lambda\omega)(\chi^2+\lambda^2)}{2(\kappa^2+\omega^2)^2}\sin\Phi. \tag{16}$$

Note here that $\sin\Phi\simeq\sqrt{\frac{2(\lambda^2+\chi^2)}{\kappa^2+\omega^2}\delta^I_{\mu\tau}}$ can be directly linked with leptogenesis through $\delta^I_{\mu\tau}$ defined in Eq. (26). Solar neutrino mixing is also presented by

$$\tan 2\theta_{12}\simeq\frac{\sqrt{2}(\kappa\chi+\omega\lambda)}{2(\kappa^2+\omega^2)}\cos\Phi. \tag{17}$$

The ratio between $\tan 2\theta_{13}$ and $\tan 2\theta_{12}$ can be approximated by the exact $\mu-\tau$ reflection parameter as

$$\frac{\tan 2\theta_{13}}{\tan 2\theta_{12}}\simeq\frac{\chi^2+\lambda^2}{(\kappa^2+\omega^2)}\tan\Phi, \tag{18}$$

which is independent of the RG correction.

From Eqs. (14-17), the Jarlskog invariant $J_{\rm CP}$ can be approximated for $\theta_{13}\ll 1$ by

$$J_{\rm CP}\simeq\frac{\sin 2\theta_{13}}{8}\sin 2\theta_{12}\simeq\frac{\delta^I_{\mu\tau}(\lambda^2+\chi^2)}{16(\kappa^2+\omega^2)^4}\{\lambda\chi(\kappa^2-\omega^2)+\kappa\omega(\lambda^2-\chi^2)\cos\Delta\phi_{12}\}, \tag{19}$$

indicating that $J_{\rm CP}$ mainly depends on θ_{12} and θ_{13}, which is in turn proportional to

$$\sin 2\Phi\simeq\frac{\delta^I_{\mu\tau}}{\delta^2_{e\mu}m_{\mu\tau}}\{\lambda\chi(\kappa^2-\omega^2)+\kappa\omega(\lambda^2-\chi^2)\cos\Delta\phi_{12}\} \tag{20}$$

defined in Eq. (13).

IV. RADIATIVELY INDUCED RESONANT LEPTOGENESIS

A. In case of the SM

Let us consider the CP asymmetry generated by the decays of the heavy Majorana neutrinos N_i (i=1, 2). In a basis where the right-handed Majorana neutrino mass matrix is real and diagonal, the CP asymmetry generated through the interference between tree and one-loop diagrams for the decay of the heavy Majorana neutrino N_i is given, for each lepton flavor α $(= e, \mu, \tau)$, by [22, 23]

$$\begin{aligned} \varepsilon_i^\alpha &= \frac{\Gamma(N_i \to l_\alpha \varphi) - \Gamma(N_i \to \bar{l}_\alpha \varphi^\dagger)}{\sum_\alpha [\Gamma(N_i \to l_\alpha \varphi) + \Gamma(N_i \to \bar{l}_\alpha \varphi^\dagger)]} \\ &= \frac{1}{8\pi (Y_\nu Y_\nu^\dagger)_{ii}} \sum_{j \neq i} \mathrm{Im}\Big\{ (Y_\nu Y_\nu^\dagger)_{ij} (Y_\nu)_{i\alpha} (Y_\nu)^*_{j\alpha} \Big\} g\Big(\frac{M_j^2}{M_i^2}\Big), \end{aligned} \tag{21}$$

where the function $g(x)$ is given by

$$g(x) = \sqrt{x}\Big[\frac{1}{1-x} + 1 - (1+x)\mathrm{ln}\frac{1+x}{x}\Big] \; . \tag{22}$$

Here i denotes a generation index and $\Gamma(N_i \to \cdots)$ is the decay width of the ith-generation right-handed neutrino. Note here that the flavor effects generated due to the term $\mathrm{Im}\Big\{ (Y_\nu Y_\nu^\dagger)_{ij} (Y_\nu)_{i\alpha} (Y_\nu)^*_{j\alpha} \Big\}$ disappears in the summation of ε_i^α for all flavors. In order for ε_i^α to be non-vanishing , not only breaking of the degeneracy of right-handed neutrinos but also non-vanishing $\mathrm{Im}[(Y_\nu Y_\nu^\dagger)_{ik}]$ and/or $\mathrm{Re}[(Y_\nu Y_\nu^\dagger)_{ik}]$ are required at a seesaw scale M.

In our scenario, we take the mass hierarchy $M_3 \gg M_1 \simeq M_2$, so that the lepton asymmetry required for a successful leptogenesis is generated from the decays of both N_1 and N_2. When two lighter heavy Majorana neutrinos are nearly degenerate, the dominant contributions to $\varepsilon^\alpha_{i(=1,2)}$ are arisen from self-energy diagrams and can be written by [22]

$$\varepsilon_i^\alpha \simeq \frac{\mathrm{Im}[\widetilde{H}_{ij} (\widetilde{Y}_\nu)_{i\alpha} (\widetilde{Y}_\nu)^*_{j\alpha}]}{16\pi (\widetilde{Y}_\nu \widetilde{Y}_\nu^\dagger)_{ii} \delta_N^{ij}} \Big(1 + \frac{\Gamma_j^2}{4M_{Ri}^2 \delta_N^{ij2}}\Big)^{-1} \; , \qquad (i \neq j) \tag{23}$$

where $\widetilde{H}_{ij}, \widetilde{Y}_\nu$ and δ_N^{ij} are defined in Eqs. (A19,A20,A24,A27) of Appendix, and the term containing decay width is negligibly small. We notice from Eq. (23) that ε_i^α is resonantly enhanced when $\Gamma_j \simeq (M_{Ri}^2 - M_{Rj}^2)/M_{Ri}$. Here, the RG evolution of the parameter δ_N^{ij} reflecting the mass splitting of the degenerate heavy Majorana neutrinos is governed by Eq. (A18). In the limit $\delta_N^{ij} \ll 1$, the leading-log approximation for δ_N^{jk} can be easily found to be

$$\delta_N^{ij} \simeq 2[\widetilde{H}_{ii} - \widetilde{H}_{jj}] \cdot t \; , \tag{24}$$

where the energy scale parameter t is defined by Eq. (A3). By using Eqs. (23,A19), ε_i^α can be expressed as

$$\begin{aligned}
\varepsilon^{e}_{1(2)} &\simeq \pm\frac{\delta^{I}_{\mu\tau}\epsilon}{16\pi\cdot h_{1(2)}}\Big\{\frac{\delta_{ee}}{\delta^{R}_{\mu\tau}}-\epsilon\frac{\delta^{\prime}_{ee}}{\delta^{R}_{\mu\tau}}\cdot t\Big\}+\mathcal{O}(t^2)~, \\
\varepsilon^{\mu}_{1(2)} &\simeq \pm\frac{\delta^{I}_{\mu\tau}\epsilon}{32\pi\cdot h_{1(2)}}\Big\{1-2\epsilon\frac{\delta^{\prime}_{\mu\tau}}{\delta^{R}_{\mu\tau}}\cdot t\Big\}+\mathcal{O}(t^2)~, \\
\varepsilon^{\tau}_{1(2)} &\simeq \pm\frac{3\delta^{I}_{\mu\tau}\epsilon}{32\pi\cdot h_{1(2)}}\Big\{1-\big(\frac{2}{3}\epsilon\frac{\delta^{\prime}_{\mu\tau}}{\delta^{R}_{\mu\tau}}+3y^2_{\tau}\big)\cdot t\Big\}+\mathcal{O}(t^2), \qquad (25)
\end{aligned}$$

where

$$\begin{aligned}
\delta_{ee} &\equiv \frac{\chi^2-\lambda^2}{2}\sin 2\alpha+\lambda\chi\cos 2\alpha~, \qquad \delta^{\prime}_{ee}\equiv(\chi^2-\lambda^2)\cos 2\alpha-2\lambda\chi\sin 2\alpha~, \\
\delta^{R}_{\mu\tau} &\equiv \frac{\kappa^2-\omega^2}{2}\sin 2\alpha+\kappa\omega\cos 2\alpha\cos\Delta\phi_{12}~, \\
\delta^{I}_{\mu\tau} &\equiv \kappa\omega\sin\Delta\phi_{12}~, \qquad \delta^{\prime}_{\mu\tau}\equiv(\kappa^2-\omega^2)\cos 2\alpha-2\kappa\omega\sin 2\alpha\cos\Delta\phi_{12}~, \qquad (26)
\end{aligned}$$

the parameter ϵ presenting RG corrections is defined in (A23) and the two parameters $h_{1(2)}$ are defined as

$$\begin{aligned}
h_1 &= \widetilde{H}_{11}/b^2_3\simeq(2\kappa^2+\chi^2)\sin^2\alpha+(\lambda^2+2\omega^2)\cos^2\alpha+\{\lambda\chi+2\kappa\omega\cos\Delta\phi_{12}\}\sin 2\alpha~, \\
h_2 &= \widetilde{H}_{22}/b^2_3\simeq(2\kappa^2+\chi^2)\cos^2\alpha+(\lambda^2+2\omega^2)\sin^2\alpha-\{\lambda\chi+2\kappa\omega\cos\Delta\phi_{12}\}\sin 2\alpha~.(27)
\end{aligned}$$

Note here that $\delta_{ee}/\delta^{R}_{\mu\tau}=-2$, which is justified from Eq. (A15), and the sign of plus and minus in Eq. (25) correspond to the case of the decay of N_1 and N_2, respectively. It is worthwhile to notice that since the angle α given by Eq. (A15) is limited by $-45^0<\alpha<45^0$, h_2 (order of 10) is always greater than h_1 (order of 1), as will be shown later. This implies that ε^{α}_1 is dominant over ε^{α}_2 because of $h_2\gg h_1$. Since the total CP asymmetries $\varepsilon_i=\sum_{\alpha}\varepsilon^{\alpha}_i$ are obtained by summing ε^{α}_i over the lepton flavors α, with the help of Eqs. (26,A15,A19,A23), we can express the lepton asymmetries as follows [2]

$$\varepsilon_{1(2)}\simeq\mp\frac{3\delta^{I}_{\mu\tau}\epsilon}{16\pi h_{1(2)}}y^2_{\tau}\cdot t~. \qquad (28)$$

where the sign of minus and plus correspond to the case of the decay of N_1 and N_2, respectively. As indicated in Eq. (23), the CP asymmetries ε^{α}_i weakly depend on the heavy Majorana neutrino scale M. From Eqs. (25,28), we see that $\varepsilon_i\propto y^4_{\tau}t$ and $\varepsilon^{\alpha}_i\propto y^2_{\tau}$. Therefore, the CP asymmetry ε^{e}_1 gets enhanced by $\varepsilon^{e}_1/\varepsilon_1\sim 2/(3y^2_{\tau}t)$ due to flavor effects [24].

---

[2] Eq. (28) can also be obtained directly by using Eq. (A27).

Below temperature $T \sim M_i \lesssim 10^9$ GeV, it is known that muon and tau charged lepton Yukawa interactions are much faster than the Hubble expansion parameter rendering the μ and τ Yukawa couplings in equilibrium. Then, the processes which wash out lepton number are flavor dependent and thus the lepton asymmetries for each flavor should be treated separately with different wash-out factors. Once the initial values of ε_i^α are fixed, the final result of η_B or Y_B can be obtained by solving a set of flavor-dependent Boltzmann equations including the decay, inverse decay, and scattering processes as well as the non-perturbative sphaleron interaction. In order to estimate the wash-out effects, we introduce the parameters K_i^α which are the wash-out factors mainly due to the inverse decay of the Majorana neutrino N_i into the lepton flavor $\alpha(=e,\mu,\tau)$ [25]. The explicit form of K_i^α is given by

$$K_i^\alpha = \frac{\Gamma(N_i \to \varphi l_\alpha)}{H(M_{Ri})} = \frac{\widetilde{m}_i^\alpha}{m_*} \ , \ \text{with} \ \ \widetilde{m}_i^\alpha = (Y_\nu^\dagger)_{\alpha i}(Y_\nu)_{i\alpha}\frac{v^2}{M_{Ri}} \ , \tag{29}$$

where $m_* \simeq 10^{-3}$ eV, and $\Gamma(N_i \to \varphi l_\alpha)$ and $H(M_{Ri})$ denote the partial decay rate of the process $N_i \to l_\alpha + \varphi^\dagger$ and the Hubble parameter at temperature $T \simeq M_{Ri}$, respectively. The decay rate of N_i to the leptons with flavor l_α is parameterized by $\widetilde{m}_i^\alpha$ and the trace $\sum_\alpha \widetilde{m}_i^\alpha$ coincides with the parameter $\widetilde{m}_i$. From Eq. (29) and Eq. (A20), the wash-out parameters are given as

$$\begin{aligned}
K_1^e &\simeq \frac{m_0}{m_*}(\chi s_\alpha + \lambda c_\alpha)^2 \ , \quad K_2^e \simeq \frac{m_0}{m_*}(\chi c_\alpha - \lambda s_\alpha)^2 \ , \\
K_1^{\mu,\tau} &\simeq \frac{m_0}{m_*}(s_\alpha^2\kappa^2 + c_\alpha^2\omega^2 + 2\kappa\omega c_\alpha s_\alpha \cos\Delta\phi_{12}) \ , \\
K_2^{\mu,\tau} &\simeq \frac{m_0}{m_*}(c_\alpha^2\kappa^2 + s_\alpha^2\omega^2 - 2\kappa\omega c_\alpha s_\alpha \cos\Delta\phi_{12}) \ .
\end{aligned} \tag{30}$$

The final baryon asymmetry Y_B is then given by [25]

$$Y_B \simeq \frac{12}{37}\sum_{N_i}\left[Y_i^e\Big(\varepsilon_i^e, \frac{151}{179}\widetilde{m}_i^e\Big) + Y_i^\mu\Big(\varepsilon_i^\mu, \frac{344}{537}\widetilde{m}_i^\mu\Big) + Y_i^\tau\Big(\varepsilon_i^\tau, \frac{344}{537}\widetilde{m}_i^\tau\Big)\right] \ . \tag{31}$$

Notice that each CP asymmetry for a single flavor given in Eq. (31) is weighted differently by the corresponding wash-out parameter given by Eq. (29), and appears with different weight in the final formula for the baryon asymmetry [25]. From our numerical estimate, we found that the wash-out factors K_i^α except for K_2^e are much greater than one indicating that corresponding lepton flavor asymmetries are strongly washed out, which is undesirable for successful leptogenesis. Since K_2^e can be much less than one and the lepton asymmetries given in Eq. (25) are the same order of magnitude, the lepton asymmetry for electron flavor in the weak wash-out regime leads to the dominant contribution to the lepton asymmetry, which can be enough to give rise to successful baryogenesis. Thus, Y_B is approximately given by

$$Y_B \simeq \frac{12}{37} Y_2^e \Big(\varepsilon_2^e, \frac{151}{179}\widetilde{m}_2^e\Big) \ , \tag{32}$$

and the magnitudes of $K_2 (= K_2^e + K_2^\mu + K_2^\tau)$ and K_2^e are approximately

$$K_2 \sim 130 - 160, \qquad K_2^e \sim 10^{-5} - 1 \ . \tag{33}$$

In the weak wash-out regime ($K_i^\alpha < 1$), the lepton asymmetry Y_2^e generated through the decay of N_2 is given by [25]

$$Y_2^e \simeq 1.5 \frac{\varepsilon_2^e}{g_*} \Big(\frac{\widetilde{m}_2}{3.3 \times 10^{-3} eV}\Big) \Big(\frac{\widetilde{m}_2^e}{3.3 \times 10^{-3} eV}\Big). \tag{34}$$

Therefore, the resulting baryon-to-photon ratio $\eta_B^{\rm f}$ can be simply given as

$$\eta_B^{\rm f} \simeq -10^{-3} \cdot \varepsilon_2^e K_2^e K_2 \ . \tag{35}$$

As will be shown later, the wash-out factor K_2^e is proportional to the low energy mixing angle θ_{13} and there is a connection between $\eta_B^{\rm f}$ and low energy neutrino observables such as θ_{13} and $J_{\rm CP}$.

On the other hand, the ratio of η_B without lepton flavor effects compared to $\eta_B^{\rm f}$ with lepton flavor effects [24] is presented by

$$\frac{\eta_B}{\eta_B^{\rm f}} \sim \frac{\varepsilon_2}{\varepsilon_2^e} \frac{1}{K_2^e (K_2)^2} \approx \frac{3 y_\tau^2}{32\pi^2} \ln\Big(\frac{M}{M_{\rm GUT}}\Big) \frac{1}{K_2^e (K_2)^2} \ . \tag{36}$$

Thus, without taking lepton flavor effects into account, the prediction of η_B is suppressed by $\sim 10^{-8}/K_2^e$, *i.e.,* $4 \sim 8$ orders of magnitude compared with $\eta_B^{\rm f}$, which is too small to give a successful leptogenesis.

B. In case of the SSM

Using the same way as in the case of the SM, we obtain from Eqs. (21,24) the lepton asymmetries for each lepton flavor expressed in terms of low energy parameters as

$$\begin{aligned}
\varepsilon^{e}_{1(2)} &\simeq \mp\frac{\delta^{I}_{\mu\tau}\epsilon}{48\pi h_{1(2)}}\Big\{\frac{\delta_{ee}}{\delta^{R}_{\mu\tau}}+\frac{2\epsilon}{3}\frac{\delta'_{ee}}{\delta^{R}_{\mu\tau}}\cdot t\Big\}+\mathcal{O}(t^2)\ , \\
\varepsilon^{\mu}_{1(2)} &\simeq \mp\frac{\delta^{I}_{\mu\tau}\epsilon}{96\pi h_{1(2)}}\Big\{1+\frac{4\epsilon}{3}\frac{\delta'_{\mu\tau}}{\delta^{R}_{\mu\tau}}\cdot t\Big\}+\mathcal{O}(t^2)\ , \\
\varepsilon^{\tau}_{1(2)} &\simeq \mp\frac{\delta^{I}_{\mu\tau}\epsilon}{32\pi h_{1(2)}}\Big\{1+2\big(y^2_{\tau}+\frac{2\epsilon}{9}\frac{\delta'_{\mu\tau}}{\delta^{R}_{\mu\tau}}\big)\cdot t\Big\}+\mathcal{O}(t^2)\ ,
\end{aligned} \tag{37}$$

where the sign of minus and plus correspond to the case of the decay of N_1 and N_2, respectively. Here, we notice that the lepton asymmetry $\varepsilon^{\alpha}_{1,2}$ is proportional to the parameter ϵ, and at the same time can be enhanced by $\tan^2\beta$, because $\epsilon\propto y^2_{\tau}=y^2_{\tau\mathrm{SM}}\tan^2\beta$ as shown in Eq. (A23). Here, we also note that in the SSM the loop function $g(x)$ in Eq. (21) and the mass splitting δ^{ij}_{N} are give by

$$g(x)=\sqrt{x}\Big[\frac{2}{1-x}-\ln\frac{1+x}{x}\Big]\ , \qquad \delta^{ij}_{N}\simeq 4[\widetilde{H}_{ii}-\widetilde{H}_{jj}]\cdot t\ , \tag{38}$$

which are different from those in the SM. Summing over the lepton flavors α in Eq. (21), the total lepton asymmetries are approximately given by

$$\varepsilon_{1(2)}\ \simeq\ \mp\frac{\delta^{I}_{\mu\tau}\epsilon}{24\pi h_{1(2)}}y^2_{\tau}\cdot t\ . \tag{39}$$

It is worthwhile to notice that the radiatively induced lepton asymmetries $\varepsilon_{1(2)}$ are proportional to $y^4_{\tau}=y^4_{\tau\mathrm{SM}}(1+\tan^2\beta)^2$, and thus for large $\tan\beta$ it can be highly enhanced and proportional to $\tan^4\beta$. Furthermore, it has an explicit dependence of the evolution scale t. These two points are already mentioned in Ref. [19]. Taking lepton flavor effects into account, in this case the final baryon asymmetry is given as [25]

$$Y_B\simeq\frac{10}{31}\sum_{N_i}\Big[Y^{e}_{i}\Big(\varepsilon^{e}_{i},\frac{93}{110}\widetilde{m}^{e}_{i}\Big)+Y^{\mu}_{i}\Big(\varepsilon^{\mu}_{i},\frac{19}{30}\widetilde{m}^{\mu}_{i}\Big)+Y^{\tau}_{i}\Big(\varepsilon^{\tau}_{i},\frac{19}{30}\widetilde{m}^{\tau}_{i}\Big)\Big]\ . \tag{40}$$

Similar to the SM, below temperatures $T\sim M_i\lesssim(1+\tan^2\beta)10^9$, muon and tau charged lepton Yukawa interactions are much faster than the Hubble expansion parameter rendering the μ and τ Yukawa couplings in equilibrium. To obtain the final baryon asymmetry survived, we should consider the wash-out factors. Similar to the SM, the magnitudes of K^{α}_{i} except for K^{e}_{2} are greater than one in our scenario. So, we will consider two cases depending on the magnitude of K^{e}_{2} : (i)$K^{e}_{2}\lesssim 1$ and $K^{\mu,\tau}_{2}>1$ and $K^{\alpha}_{1}>1$, (ii) $K^{\alpha}_{1(2)}>1$.

1. In case of $K_2^e \lesssim 1$ and $K_2^{\mu,\tau} > 1$ and $K_1^\alpha > 1$ $(\alpha = e, \mu, \tau)$

This case implies that the muon and tau lepton asymmetries are strongly washed out, whereas the electron asymmetry generated through the decay of N_2 is weakly washed out. The form of Y_2^e in the weak wash-out regime in the SSM is the same as that in the SM given by Eq. (34). In this case, similar to the SM, the contribution of Y_2^e to Y_B is dominant over the others. Thus, Y_B is approximately give by

$$Y_B \simeq \frac{10}{31} Y_2^e \Big(\varepsilon_2^e, \frac{93}{110}\widetilde{m}_2^e\Big) \ , \tag{41}$$

and the magnitudes of K_2 and K_2^e are approximately

$$K_2 \sim 80 \ (\tan\beta = 1), \quad \sim 40 \ (\tan\beta = 10 - 60) \ , \qquad K_2^e \sim 10^{-5} - 1 \ . \tag{42}$$

The resulting baryon-to-photon ratio $\eta_B^{\rm f}$ is simply given as

$$\eta_B^{\rm f} \simeq -10^{-3} \cdot \varepsilon_2^e K_2^e K_2 \ . \tag{43}$$

Just like the SM, one can see that there is a connection between baryon asymmetry and low energy neutrino observables. The ratio of η_B without lepton flavor effects to $\eta_B^{\rm f}$ with lepton flavor effects are simply given by [24]

$$\frac{\eta_B}{\eta_B^{\rm f}} \sim \frac{\varepsilon_2}{\varepsilon_2^e}\frac{1}{K_2^e (K_2)^2} \approx \frac{y_\tau^2}{16\pi^2} \ln\Big(\frac{M}{M_{\rm GUT}}\Big)\frac{1}{K_2^e (K_2)^2} \ . \tag{44}$$

From this result, we see that without taking lepton flavor effects into account the prediction of η_B is suppressed by $\sim 10^{-8}(1+\tan^2\beta)/K_2^e$, compared with $\eta_B^{\rm f}$. However, on the contrary to the flavor independent leptogenesis in the SM, it is possible to get a right amount of baryon asymmetry without flavor effects for the case of large $\tan\beta$ (~ 60).

2. In case of $K_{1,2}^\alpha > 1$, $(\alpha = e, \mu, \tau)$

In the strong wash-out regime $K_{1,2}^\alpha > 1$ $(\alpha = e, \mu, \tau)$, the lepton asymmetry for the flavor l_α generated through the decay of N_i is given by [25]

$$Y_i^\alpha \ \simeq \ 0.3 \frac{\varepsilon_i^\alpha}{g_*}\Big(\frac{0.55 \times 10^{-3} eV}{\widetilde{m}_i^\alpha}\Big)^{1.16} . \tag{45}$$

In this case, given the initial thermal abundance of N_i and the condition for K_i^α, the baryon asymmetry including lepton flavor effects is approximately given by [26]

$$\eta_B^{\rm f} \simeq -10^{-2} \sum_i \sum_\alpha \varepsilon_i^\alpha \kappa_i^\alpha \ , \quad \text{with } \kappa_i^\alpha \equiv \frac{K_i^\alpha}{K_i K^\alpha} \ . \tag{46}$$

Here, we note that each lepton asymmetry ε_i^α are almost the same order of magnitudes, even though ε_1^τ for large $\tan\beta$ and ε_1^e for small $\tan\beta$ are slightly dominant within a few factors. According to our numerical estimate, the typical sizes of the suppression factors κ_i^α are

$$\begin{aligned} \kappa_1^e &\sim\ 10^{-1} > \kappa_2^{\mu,\tau} \sim 2\times10^{-2} \gtrsim \kappa_1^{\mu,\tau} > \kappa_2^e \sim 10^{-2} \qquad \text{for } \tan\beta \gtrsim 3, \\ \kappa_1^e &\sim\ 5\times10^{-1} > \kappa_2^{\mu,\tau} \sim 10^{-2} \gtrsim \kappa_1^{\mu,\tau} > \kappa_2^e \sim 4\times10^{-3} \ \ \text{for } \tan\beta < 3 \ , \end{aligned} \tag{47}$$

which indicates that the flavor dependent wash-out factors equally contribute to leptogenesis.

Using Eq. (47), the resulting baryon-to-photon ratio $\eta_B^{\rm f}$ can be simply approximated as an order of magnitude

$$\eta_B^{\rm f} \sim 10^{-11}(1+\tan^2\beta) \ , \tag{48}$$

which represents that at least $\tan\beta \gtrsim 7$ is needed for the flavored leptogenesis to successfully work (see, Fig. 6 in sec. V).

As a consequence, in the strong wash-out case, the resulting baryon asymmetry is too small to give a successful leptogenesis in the SM, whereas at least $\tan\beta \gtrsim 7$ would be necessary to accommodate required baryon asymmetry in the SSM, and there exists also a connection between leptogenesis and low energy observable θ_{12}. Note that the strong wash-out case only allow θ_{13} to be $\gtrsim 6°$ which is from the condition $K_2^e > 1$.

V. NUMERICAL ANALYSIS AND RESULTS

In order to estimate the RG evolutions of neutrino Dirac-Yukawa matrix and heavy Majorana neutrino masses from the GUT scale to a seesaw scale, we numerically solve all the relevant RG equations presented in [13]. In our numerical calculation of the RG evolutions, we first fix the values of two masses of heavy Majorana neutrinos with hierarchy $M_3 \gg M_1 = M_2 = M$ to be $M_3 = 10^{12}$ GeV, and $M_2 = 5\times10^6$ GeV as inputs[3]. Then we solve the RG equations by varying input values of all the parameter space $\{b_3, \kappa, \omega, \lambda, \chi, \phi_1, \phi_2\}$ given at the GUT scale. Then, finally we select the parameter space allowed by low energy neutrino experimental data. At present, we have five experimental data, which are taken as low energy constraints in our numerical analysis, given at 3σ by [27],

---

[3] We note that the mass M can be as light as 10^3 GeV in our scenario.

$$\begin{aligned} &0.26 \leq \sin^2\theta_{12} \leq 0.40~, \qquad 0.34 \leq \sin^2\theta_{23} \leq 0.67~, \qquad \sin^2\theta_{13} \leq 0.050, \\ &2.0 \leq \Delta m^2_{\rm Atm}[10^{-3}{\rm eV}^2] \leq 2.8~, \qquad 7.1 \leq \Delta m^2_{\rm Sol}[10^{-5}{\rm eV}^2] \leq 8.3, \end{aligned} \tag{49}$$

where $\Delta m^2_{\rm Atm} \equiv m_3^2 - m_2^2$ and $\Delta m^2_{\rm Sol} \equiv m_2^2 - m_1^2$. In addition, the current measurement of baryon asymmetry of our universe $\eta_B^{\rm exp}$ we take in our numerical calculation is given by [28]

$$\eta_B^{\rm exp} = (6.2 \pm 0.15) \times 10^{-10}. \tag{50}$$

Using the results of the RG evolutions, we estimate baryon asymmetry for the parameter space constrained from the low energy experimental data.

A. In case of $K_2^e \lesssim 1$ and $K_2^{\mu,\tau} > 1$ and $K_1^\alpha > 1$ $(\alpha = e, \mu, \tau)$

For this case of wash-out factors, we found that baryogenesis could be successfully implemented in the SM and the SSM through electron flavor dominant leptogenesis. In addition, we show that the successful leptogenesis could be linked with low energy observables (θ_{13} and $J_{\rm CP}$) through the RG parameter ϵ given in Eq. (A23) as well as K_2^e.

In Fig. 1, we show the scatter plots for the model parameters in the SM (upper panel) and the SSM ($\tan\beta = 10$) (lower panel) constrained by the experimental data given in Eq. (49): the figures in the left-hand side exhibit how the parameters κ (triangles), ω (circles), λ (asters) and χ(crosses) are correlated with the angle α defined in Eq. (A15), respectively and the figures in the right-hand side represent how the difference between the phases ϕ_1 and ϕ_2 in Eq. (3), $|\Delta\phi|$ $(= |\phi_2 - \phi_1|)$, depends on the angle α .

In Fig. 2, we present how the wash-out factor K_2^e (Fig. 2-a) and CP violating observable $J_{\rm CP}$ (Fig. 2-b) are correlated with the mixing angle θ_{13}. The circles, triangles, stars and spots in Fig. 2 correspond to the cases of the SM, and the SSM with $\tan\beta = 1$, $\tan\beta = 10$ and $\tan\beta = 60$, respectively. From Fig. 2-(a), we see that in the case $K_2^e < 1$ (weak wash-out regime) the mixing angle θ_{13} is limited. Even in the case of the SSM with $\tan\beta = 60$, the upper limit of θ_{13} is about 9 degree. It is remarkable from Fig. 2-(a) that $\eta_B^{\rm f}$ is expected to

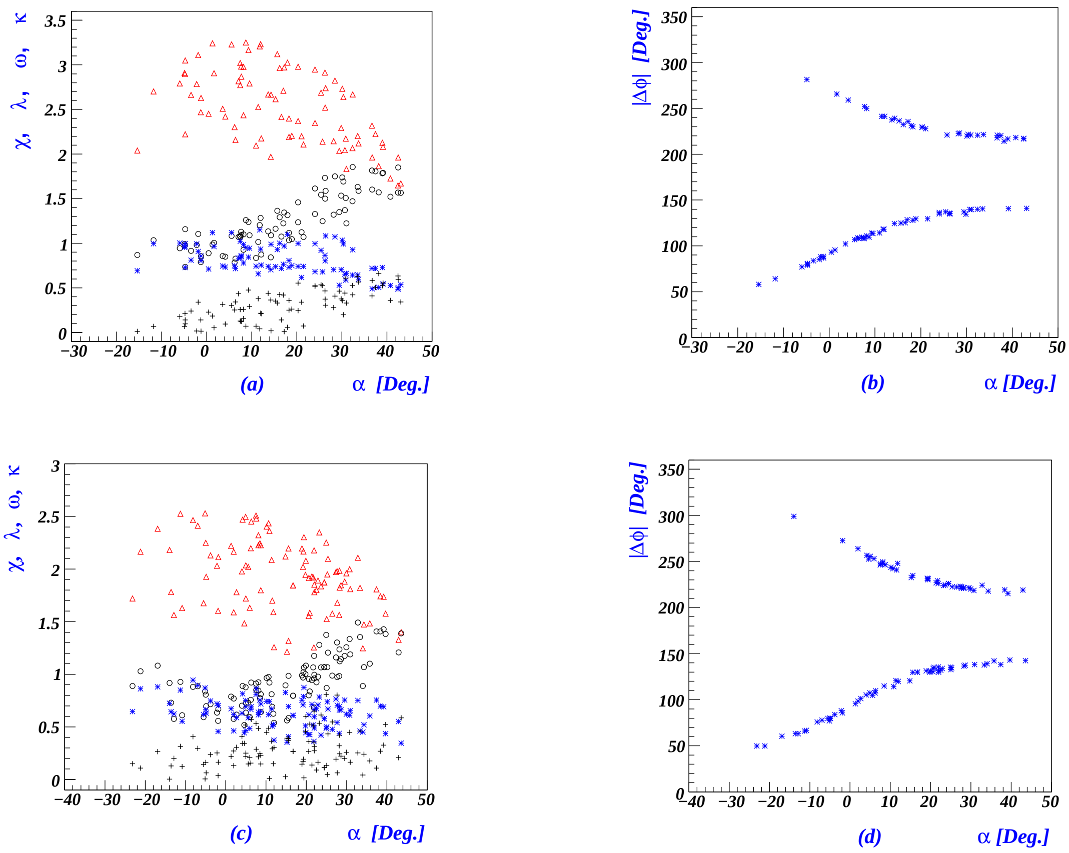

FIG. 1: Parameter regions allowed by the experimental constraints at 3σ C.L. given in Eq. (49) for $M_3 = 10^{12}$ GeV, $M_2 = 5 \times 10^6$ GeV. The figures in left-hand side exhibit how the parameters κ(triangles), ω(circles), λ(asters) and χ(crosses) are correlated with the angle α, respectively and the figures in right-hand side represent how $|\Delta\phi|$ depends on the angle α, where $\Delta\phi = \phi_2 - \phi_1$, among the phases assigned in the neutrino Dirac-Yukawa matrix given in the form of Eq. (3). Upper panels correspond to the case of the SM, whereas lower panels correspond to the case of the SSM for $\tan\beta = 10$.

be enhanced through K_2^e as θ_{13} gets lower. Thus, this case with $K_2^e < 1$ favors low values of θ_{13}. The vertical dotted lines in Fig. 2-(b) indicate the values of θ_{13} corresponding to best-fit value of baryon asymmetry of our universe, *i.e.* $\eta_B^{\mathrm{exp-BT}} = 6.2 \times 10^{-10}$, when $\tan\beta = 1, 10$ and 60, respectively, whereas the vertical solid line corresponds to the case of the SM. As can be seen in Fig. 2-(b), the prediction of J_{CP} for the SSM with a low $\tan\beta$ can be measurable in the near future from long baseline neutrino oscillations.

In Fig. 3, we present the predictions of (a) η_B^{f} and (b) η_B for the SM (triangle), the

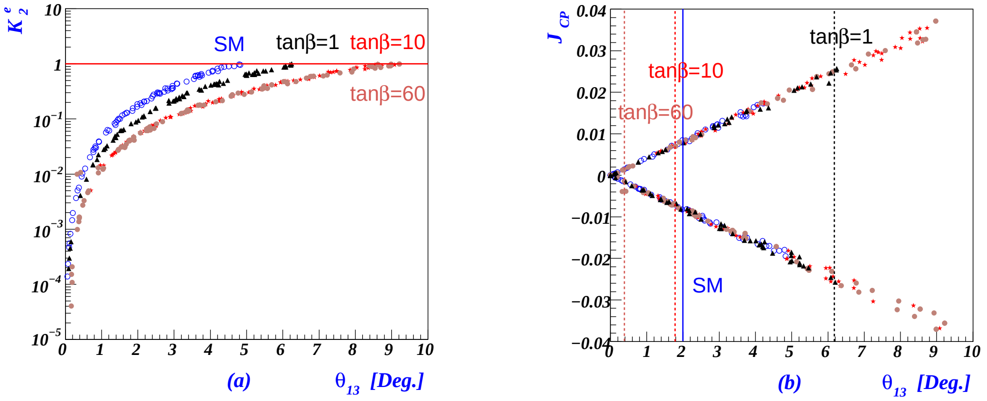

FIG. 2: Plots of wash-out parameter K_2^e (a) and $J_{\rm CP}$ as a function of θ_{13} for the SM (circles), the SSM with $\tan\beta = 1$ (triangles), 10 (stars), 60 (spots). The vertical dotted lines indicate the values of θ_{13} corresponding to the best-fit value of η_B for $\tan\beta = 1, 10$ and 60, respectively, whereas the vertical solid line corresponds to the case of the SM.

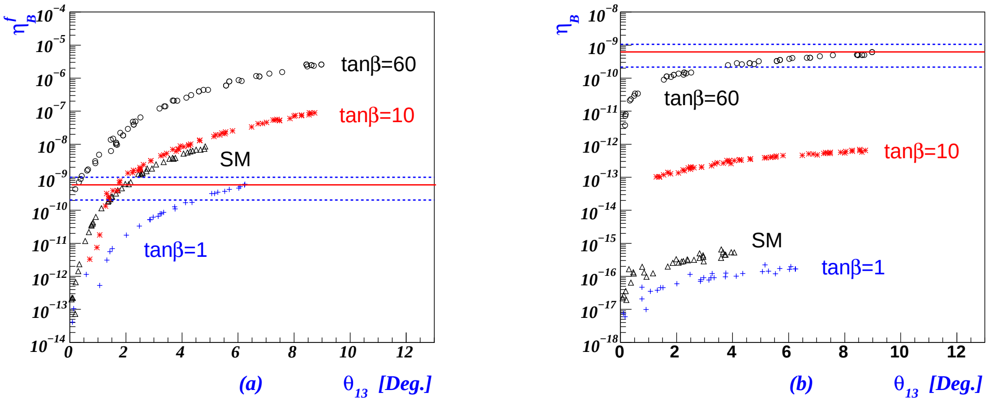

FIG. 3: Predictions for the baryon asymmetries (a) η_B^f and (b) η_B as a function of θ_{13} for the same parameter space as in Fig. 1. The horizontal dotted lines and solid line in Fig. 3 (also in Figs. 4 and Fig. 6) correspond to the current bounds on η_B, measured from the current astrophysical observations [28].

SSM with $\tan\beta = 1$ (daggers), 10 (asters) and 60 (circles) as a function of the mixing angle θ_{13}. In the case of flavor dependent leptogenesis, the allowed values of $\eta_B^{\rm f}$ prefers very low values of θ_{13}. The horizontal dotted lines and solid line in Fig. 3 (also in Figs. 4 and Fig. 6) correspond to the current bounds on η_B. We see from Fig. 3 that the prediction of $\eta_B^{\rm f}$ in

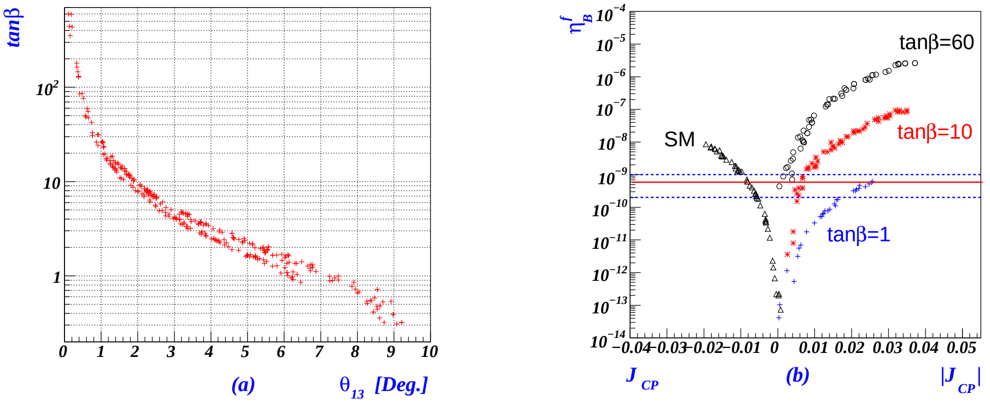

FIG. 4: (a) Predictions of $\tan\beta$ in terms of θ_{13} for flavored leptogenesis. (b) A link between $\eta_B^{\rm f}$ and $J_{\rm CP}$ and $|J_{\rm CP}|$ for the SM and the SSM, respectively.

the SSM for a fixed θ_{13} is increased as $\tan\beta$ increases. As explained with Eq. (44), we see from Fig. 3 that η_B is suppressed by factor $4 \sim 8$ compared with $\eta_B^{\rm f}$ because of the different wash-out factors presented in Eq. (30). We also see from Fig. 3 that a successful baryogenesis can be achieved via flavor dependent leptogenesis in both the SM and the SSM, whereas a successful baryogenesis via flavor independent leptogenesis is possible only for the SSM with large $\tan\beta$ (~ 60). For this case, we can obtain lower limit of $\tan\beta$ from the current observation for η_B based on Eqs. (11,27,A19,A23) as follows;

$$\tan\beta \gtrsim \Big(\frac{2\times 10^3}{t}\Big[\frac{\tilde{\delta}h_1}{\delta^R_{\mu\tau}\delta^I_{\mu\tau}}\Big]\Big)^{1/4} . \tag{51}$$

Imposing the best-fit value of observed baryon asymmetry, θ_{13} is determined to be 2° for the SM and 6.2°, 1.8° and 0.4° for the SSM with $\tan\beta = 1, 10$ and 60, respectively. For the case $K_2^e < 1$, the dominant contribution to $\eta_B^{\rm f}$ comes from the e-leptogenesis η_B^e, as shown in Eq. (43). In the case of the SSM, the value of θ_{13} corresponding to $\eta_B^{\rm exp-BT}$ becomes lower as $\tan\beta$ gets higher because K_2^e is proportional to θ_{13}. From Eqs. (25,43,50), we can roughly get the value of $\tan\beta$ corresponding to $\eta_B^{\rm exp-BT}$ as follows:

$$\tan\beta \simeq \Big(\frac{0.1}{K_2^e K_2}\Big[\frac{\tilde{\delta}h_2}{\delta^R_{\mu\tau}\delta^I_{\mu\tau}}\Big] - 1\Big)^{1/2} . \tag{52}$$

In Fig. 4-(a), we present how $\tan\beta$ is correlated with the mixing angle θ_{13}, which reflects the above equation (52). Fig. 4-(b) shows how the baryon asymmetry $\eta_B^{\rm f}$ is sensitive to the CP violating observable $J_{\rm CP}$ given by Eq. (19). The triangles, daggers, asters and circles

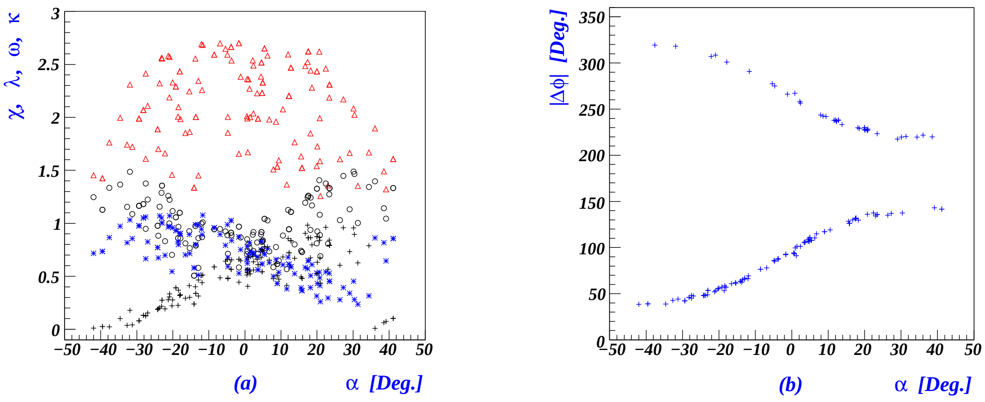

FIG. 5: The same as Fig. 1 for $\tan\beta = 10$ except for $K_i^\alpha > 1$.

correspond to the cases of the SM and the SSM with $\tan\beta = 1, 10, 60$, respectively. The value of $\eta_B^{\rm f}$ corresponding to $\eta_B^{\rm exp-BT}$ for the case of the SM leads to $|J_{\rm CP}| \simeq 0.008$ (and $\theta_{13} \simeq 2^\circ$), which can be measured in the future long-baseline neutrino oscillation experiments. From Fig. 4-(b) and Fig. 2-(b), we see that the value of $J_{\rm CP}$ corresponding to $\eta_B^{\rm exp-BT}$ for the case of the SSM becomes higher as $\tan\beta$ gets smaller. Thus, if future experiments can measure $J_{\rm CP}$ with a sensitivity better than 0.01, the predictions of $\eta_B^{\rm f}$ in the SSM with low $\tan\beta$ (< 10) could be probed.

B. In case of $K_{1,2}^\alpha > 1$, ($\alpha = e, \mu, \tau$)

In the case of strong wash-out for the decay of $N_{1,2}$, $K_{1,2}^{e,\mu,\tau} > 1$, it turns out that baryogenesis in the SM cannot be successfully realized. However, as can be seen in Eq. (48), flavor dependent leptogenesis in the SSM could successfully be implemented at least for $\tan\beta \gtrsim 7$ as explained below. In Fig. 5, we show the scatter plots for the model parameters in the SSM with $\tan\beta = 10$ constrained by the experimental data given in Eq. (49): Fig. 5-(a) exhibits how the parameters κ (triangles), ω (circles), λ (asters) and χ (crosses) are correlated with the angle α defined in Eq. (A15), respectively. Fig. 5-(b) represents how $|\Delta\phi|$ depends on the angle α. Fig. 6 presents the predictions of baryon asymmetry for the allowed parameter regions presented in Fig. 5 as a function of (a) the solar mixing angle θ_{12} and (b) the CHOOZ mixing angle θ_{13}. The results indicate that in the SSM flavor dependent leptogenesis can successfully work out for $\tan\beta \gtrsim 10$, whereas flavor independent leptogenesis does so only

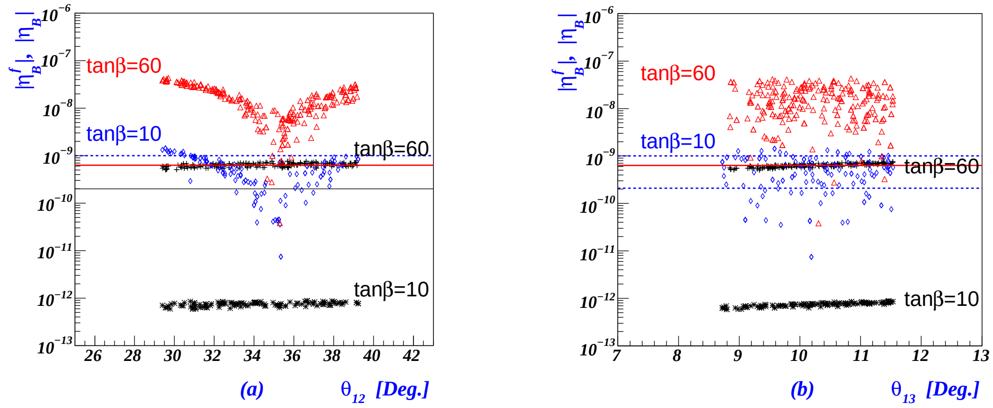

FIG. 6: Predictions for the baryon asymmetry as a function of (a) θ_{12} and (b) θ_{13} for the same parameter space as in Fig. 5 in the strong wash-out limit. The triangles and diamonds (daggers and asters) correspond to flavored (unflavored) leptogenesis for $\tan\beta = 60$ and 10, respectively.

for the SSM with $\tan\beta \sim 60$.

From Eqs. (25,46,50), we can get the relation,

$$\tan\beta \simeq \left(\frac{\eta_B^{\rm best-fit}}{x y^2_{\tau {\rm SM}}} - 1\right)^{1/2} , \tag{53}$$

where $x = \eta^{\rm f}_B / y^2_\tau$. The relation given by Eq. (53) indicates that there exits a correlation between $\tan\beta$ and θ_{12} for a fixed value of η_B. In particular, taking $\eta_B = \eta_B^{\rm exp-BT}$, we plot the correlation between $\tan\beta$ and θ_{12} in Fig. 7-(b). From our numerical estimate, we found

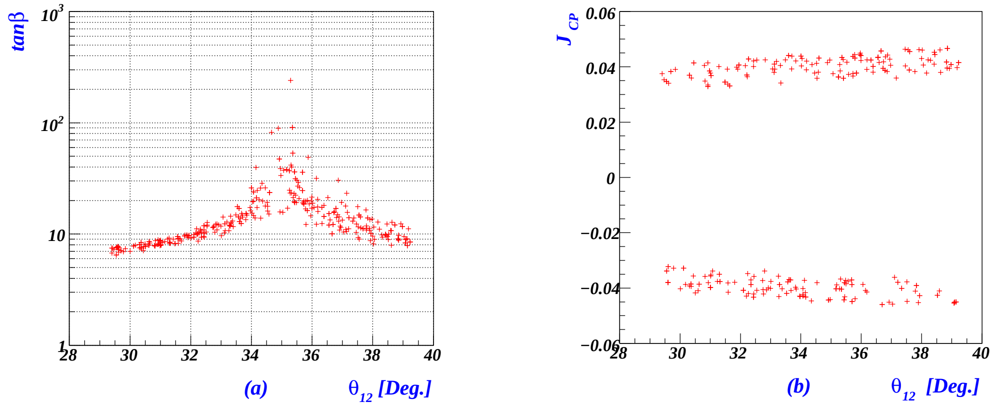

FIG. 7: (a) Plot presenting how $\tan\beta$ is sensitive to θ_{12} for flavored leptogenesis. (b) The relationship between $J_{\rm CP}$ and θ_{12} mentioned in Eq. (19).

that in order for the prediction of $\eta_B^{\rm f}$ in the case of strong wash-out to be consistent with the right amount of baryon asymmetry given by Eq. (50) the value of $\tan\beta$ should be

$$\tan\beta \gtrsim 7 \ . \tag{54}$$

Thus, future measurements for $\tan\beta$ and θ_{12} could serve as an indirect test for the scenario of baryogenesis considered in this paper. Fig. 7-(b) represents the correlation between $J_{\rm CP}$ and θ_{12} for a fixed value of $\eta_B(=\eta^{\rm exp-BT})$. The results show that the best fit value of η_B and the current measurement of θ_{12} favors $|J_{\rm CP}| \simeq 0.04$ which can be measurable in the upcoming long baseline neutrino oscillation experiments.

VI. SUMMARY

As a summary, we have considered an exact $\mu-\tau$ reflection symmetry in neutrino sector realized at the GUT scale in the context of the seesaw model. The exact $\mu-\tau$ reflection symmetry has been imposed in the basis where both the charged lepton mass and heavy Majorana neutrino mass matrices are real and diagonal. We have assumed that the two lighter heavy Majorana neutrinos are degenerate at the GUT scale. It has been shown that the RG evolution from the GUT scale to the seesaw scale gives rise to breaking of the $\mu-\tau$ symmetry and a tiny splitting between two degenerate heavy Majorana neutrino masses as well as small variations of the CP phases in Y_ν, which are essential to achieve a successful leptogenesis. Such small RG effects lead to tiny deviations of θ_{23} from the maximal value and the CP phase $\delta_{\rm CP}$ from $\frac{\pi}{2}$ imposed at the GUT scale due to $\mu-\tau$ reflection symmetry. In our scenario, the required amount of the baryon asymmetry η_B could be generated via so-called resonant e-leptogenesis, in which the wash-out factor concerned with electron flavor plays a crucial role in reproducing a successful leptogenesis. And we have found that the magnitude of the electron leptogenesis is enhanced by $4\sim 8$ orders due to the flavor effects in the SM, and enhanced further by a factor of $\tan^2\beta$ for the SSM.

A point deserved to notice is that CP violation responsible for the generation of baryon asymmetry of our universe comes from the breaking of both the two degenerate heavy Majorana neutrinos and the CP phases $\phi_{1,2}$ in Y_ν by RG evolutions, which corresponds to the tiny breakdown of $\mu-\tau$ reflection symmetry, and such small RG effects cause leptogenesis to directly be linked with the CP violation measurable through neutrino oscillation as well as neutrino mixing angles θ_{12} and θ_{13}. We expect that in addition to the reactor and long baseline neutrino experiments for precise measurements of neutrino mixing angles and CP violation, the measurements for the supersymmetric parameter $\tan\beta$ at future collider experiments would serve as an indirect test of our scenario of baryogenesis based on the $\mu-\tau$ reflection symmetry.

APPENDIX A: RELEVANT RENORMALIZATION GROUP EQUATIONS

A non-zero leptonic asymmetry can be generated if and only if the CP odd invariants $\tilde{J}_{CP} = \mathrm{ImTr}[H\mathbf{M}_R^\dagger \mathbf{M}_R \mathbf{M}_R^\dagger H^T \mathbf{M}_R]$ does not vanish [17, 29]. Since $\tilde{J}_{CP}$ can be expressed in the form

$$\tilde{J}_{\mathrm{CP}} = 2\sum_{i<j}\Big\{M_i M_j (M_j^2 - M_i^2)\mathrm{Im}[H_{ij}]\mathrm{Re}[H_{ij}]\Big\}, \quad H \equiv \mathbf{Y}_\nu \mathbf{Y}_\nu^\dagger \ , \tag{A1}$$

which is relevant for leptogenesis [17], a non-vanishing leptonic asymmetry requires not only $M_i \neq M_j$ but also $\mathrm{Im}[H_{ij}]\mathrm{Re}[H_{ij}] \neq 0, (i \neq j = 1, 2, 3)$, at the leptogenesis scale. Even if we start from exact degeneracy between the two light heavy Majorana neutrinos (N_1, N_2) at a certain high energy scale, it is likely to see that some splitting in their masses could be induced at a different scale (seesaw scale) through RG running effects. And the Dirac neutrino Yukawa matrix $\mathbf{Y}_\nu$ is also modified by the same RG effect, which is very important to obtain nonzero $\mathrm{Im}[H_{ij}]\mathrm{Re}[H_{ij}] \neq 0$, as will be shown later.

The radiative behavior of the heavy Majorana neutrinos mass matrix $\mathbf{M}_R$ is dictated by the following RG equations [15]:

$$\begin{aligned} \frac{d\mathbf{M}_R}{dt} &= [(\mathbf{Y}_\nu \mathbf{Y}_\nu^\dagger)\mathbf{M}_R + \mathbf{M}_R(\mathbf{Y}_\nu \mathbf{Y}_\nu^\dagger)^T] \ , \quad \mathrm{SM} \\ \frac{d\mathbf{M}_R}{dt} &= 2[(\mathbf{Y}_\nu \mathbf{Y}_\nu^\dagger)\mathbf{M}_R + \mathbf{M}_R(\mathbf{Y}_\nu \mathbf{Y}_\nu^\dagger)^T] \ , \quad \mathrm{SSM} \end{aligned} \tag{A2}$$

where

$$t = \frac{1}{16\pi^2}\ln(Q/M_{\mathrm{GUT}}) \tag{A3}$$

with an arbitrary renormalization scale Q. The RG equations for the Dirac-Yukawa neutrino matrix can be written as

$$\begin{aligned} \frac{d\mathbf{Y}_\nu}{dt} &= \mathbf{Y}_\nu[(T - \frac{3}{4}g_2^2 - \frac{9}{4}g_1^2) - \frac{3}{2}(\mathbf{Y}_l^\dagger \mathbf{Y}_l - \mathbf{Y}_\nu^\dagger \mathbf{Y}_\nu)] \ , \quad \mathrm{SM} \\ \frac{d\mathbf{Y}_\nu}{dt} &= \mathbf{Y}_\nu[(T - 3g_2^2 - \frac{3}{5}g_1^2) + \mathbf{Y}_l^\dagger \mathbf{Y}_l + 3\mathbf{Y}_\nu^\dagger \mathbf{Y}_\nu \ , \qquad \mathrm{SSM} \end{aligned} \tag{A4}$$

where $T = Tr(3Y_u^\dagger Y_u + \mathbf{Y}_\nu^\dagger \mathbf{Y}_\nu)$, Y_u and $\mathbf{Y}_l$ are the Yukawa matrices for up-type quarks and charged leptons and $g_{2,1}$ are the $\mathrm{SU}(2)_L$ and $\mathrm{U}(1)_Y$ gauge coupling constants.

Let us first reformulate the RG equations (A2) in the basis where $\mathbf{M}_R$ is diagonal. Since $\mathbf{M}_R$ is symmetric, it can be diagonalized by a unitary matrix V,

$$V^T \mathbf{M}_R V = \mathrm{Diag.}(M_1, M_2, M_3). \tag{A5}$$

As the structure of the mass matrix $\mathbf{M}_R$ changes with the evolution of the scale, the unitary matrix V depends on the scale, too. The RG evolution of the matrix $V(t)$ can be written as

$$\frac{d}{dt}V = VA, \tag{A6}$$

where A is an anti-Hermitian matrix $A^\dagger = -A$ due to the unitary of V. Then, differentiating Eq. (A5), we obtain

$$\begin{aligned}
\frac{dM_i\delta_{ij}}{dt} &= A^T_{ij}M_j + M_iA_{ij} + \{V^T[(\mathbf{Y}_\nu\mathbf{Y}^\dagger_\nu)\mathbf{M}_R + \mathbf{M}_R(\mathbf{Y}_\nu\mathbf{Y}^\dagger_\nu)^T]V\}_{ij} \ , \quad \text{SM} \\
\frac{dM_i\delta_{ij}}{dt} &= A^T_{ij}M_j + M_iA_{ij} + 2\{V^T[(\mathbf{Y}_\nu\mathbf{Y}^\dagger_\nu)\mathbf{M}_R + \mathbf{M}_R(\mathbf{Y}_\nu\mathbf{Y}^\dagger_\nu)^T]V\}_{ij} \ , \quad \text{SSM.}
\end{aligned} \tag{A7}$$

Absorbing the unitary transformation into the Dirac-Yukawa coupling $Y_\nu \equiv V^T\mathbf{Y}_\nu$, the real diagonal part of Eq. (A7) becomes

$$\begin{aligned}
\frac{dM_i}{dt} &= 2M_i(Y_\nu Y^\dagger_\nu)_{ii} \ , \quad \text{SM} \\
\frac{dM_i}{dt} &= 4M_i(Y_\nu Y^\dagger_\nu)_{ii} \ , \quad \text{SSM.}
\end{aligned} \tag{A8}$$

The off diagonal part of Eq. (A7) leads to

$$\begin{aligned}
A_{ij} &= \frac{M_j + M_i}{M_j - M_i}\mathrm{Re}[(Y_\nu Y^\dagger_\nu)_{ij}] + i\frac{M_j - M_i}{M_j + M_i}\mathrm{Im}[(Y_\nu Y^\dagger_\nu)_{ij}] \ , \qquad \text{SM} \\
A_{ij} &= 2\frac{M_j + M_i}{M_j - M_i}\mathrm{Re}[(Y_\nu Y^\dagger_\nu)_{ij}] + i2\frac{M_j - M_i}{M_j + M_i}\mathrm{Im}[(Y_\nu Y^\dagger_\nu)_{ij}] \ , \quad \text{SSM.}
\end{aligned} \tag{A9}$$

The RG equations for Y_ν in the basis where $\mathbf{M}_R$ are diagonal is written as

$$\begin{aligned}
\frac{dY_\nu}{dt} &= Y_\nu[(T - \frac{3}{4}g_2^2 - \frac{9}{4}g_1^2) - \frac{3}{2}(\mathbf{Y}^\dagger_l\mathbf{Y}_l - Y^\dagger_\nu Y_\nu)] + A^TY_\nu \ , \quad \text{SM} \\
\frac{dY_\nu}{dt} &= Y_\nu[(T - 3g_2^2 - \frac{3}{5}g_1^2) + \mathbf{Y}^\dagger_l\mathbf{Y}_l + 3Y^\dagger_\nu Y_\nu)] + A^TY_\nu \ , \qquad \text{SSM.}
\end{aligned} \tag{A10}$$

The RG equations for the quantity H relevant for leptogenesis can be written as

$$\begin{aligned}
\frac{dH}{dt} &= 2\big(T - \frac{3}{4}g_2^2 - \frac{9}{4}g_1^2\big)H - 3Y_\nu(\mathbf{Y}^\dagger_l\mathbf{Y}_l)Y^\dagger_\nu + 3H^2 + A^TH + HA^* \ , \ \text{SM} \\
\frac{dH}{dt} &= 2\big(T - 3g_2^2 - \frac{3}{5}g_1^2\big)H + 2Y_\nu(\mathbf{Y}^\dagger_l\mathbf{Y}_l)Y^\dagger_\nu + 6H^2 + A^TH + HA^* \ , \quad \text{SSM.}
\end{aligned} \tag{A11}$$

We see from Eq. (A9) that the real part of A_{ij} is singular when $M_i = M_j$. The singularity in $\mathrm{Re}[A_{ij}]$ can be eliminated with the help of an appropriate rotation between degenerate heavy Majorana neutrino states. Such a rotation does not change any physics and it is equivalent to absorb the rotation matrix R into the Dirac-Yukawa neutrino matrix Y_ν,

$$Y_\nu \longrightarrow \widetilde{Y}_\nu = RY_\nu, \tag{A12}$$

where the matrix R, in our case, particularly rotating the 1st and 2rd generations of heavy Majorana neutrinos can be parameterized as

$$R(\alpha) = \begin{pmatrix} \cos\alpha & \sin\alpha & 0 \\ -\sin\alpha & \cos\alpha & 0 \\ 0 & 0 & 1 \end{pmatrix} . \tag{A13}$$

Then, the singularity in the real part of A_{ij} is indeed removed when the rotation angle α is taken to be satisfied with the condition,

$$\mathrm{Re}[(\widetilde{Y}_\nu \widetilde{Y}_\nu^\dagger)_{ij}] = 0 \ , \quad \text{for any pair } i, j \text{ corresponding to } M_i = M_j \ , \tag{A14}$$

for $i, j = 1, 2$, which leads to

$$\tan 2\alpha \ = \ \frac{2H_{12}}{H_{11} - H_{22}} = \frac{2(\lambda\chi + 2\omega\kappa\cos\Delta\phi_{12})}{\lambda^2 + 2\omega^2 - \chi^2 - 2\kappa^2} \ . \tag{A15}$$

With $\widetilde{Y}_\nu$, we construct a parameter $\widetilde{H}$ as follows;

$$\widetilde{H} \ \equiv \ \widetilde{Y}_\nu \widetilde{Y}_\nu^\dagger = RHR^T = \begin{pmatrix} \widetilde{H}_{11} & 0 & \widetilde{H}_{13} \\ 0 & \widetilde{H}_{22} & \widetilde{H}_{23} \\ \widetilde{H}_{13} & \widetilde{H}_{23} & H_{33} \end{pmatrix} , \tag{A16}$$

where $H = Y_\nu Y_\nu^\dagger$ and the components of $\widetilde{H}$ are given by

$$\begin{aligned} \widetilde{H}_{11} \ &= \ H_{11}\cos^2\alpha + H_{12}\sin 2\alpha + H_{22}\sin^2\alpha \ , \qquad \widetilde{H}_{13} = H_{13}\cos\alpha + H_{23}\sin\alpha \ , \\ \widetilde{H}_{22} \ &= \ H_{22}\cos^2\alpha - H_{12}\sin 2\alpha + H_{11}\sin^2\alpha \ , \qquad \widetilde{H}_{23} = H_{23}\cos\alpha - H_{13}\sin\alpha \ . \end{aligned}$$

It is then obvious from Eq. (A16) that $\mathrm{Re}[(\widetilde{Y}_\nu \widetilde{Y}_\nu^\dagger)_{12(21)}] = 0$ and thus the singularity in $A_{12(21)}$ does not appear.

Now, let us consider RG effects which may play an important role in successful leptogenesis. First, we parameterize the mass splitting of the degenerate heavy Majorana neutrinos in terms of a parameter δ_N defined by

$$\delta_N \equiv 1 - \frac{M_2}{M_1}, \tag{A17}$$

which is governed by the following RG equations derived from Eq. (A8),

$$\begin{aligned} \frac{d\delta_N}{dt} \ &= \ 2(1-\delta_N)[\widetilde{H}_{11} - \widetilde{H}_{22}] \simeq \frac{4H_{12}}{\sin 2\alpha} \ , \qquad \text{SM} \\ \frac{d\delta_N}{dt} \ &= \ 4(1-\delta_N)[\widetilde{H}_{11} - \widetilde{H}_{22}] \simeq \frac{8H_{12}}{\sin 2\alpha} \ , \qquad \text{SSM.} \end{aligned} \tag{A18}$$

The solutions of the RG equations (A18) are approximately given by

$$\delta_N \simeq \begin{cases} b_3^2\tilde{\delta}\cdot t, & \text{SM} , \\ 2b_3^2\tilde{\delta}\cdot t, & \text{SSM} , \end{cases} \qquad \text{with} \;\; \tilde{\delta} = \frac{4(\lambda\chi + 2\omega\kappa\cos\Delta\phi_{12})}{\sin 2\alpha}, \tag{A19}$$

where we used the parameters defined in Eq. (4).

Next, we consider RG running of the Dirac neutrino Yukawa matrix from the GUT scale to the seesaw scale, $Q \simeq M$. Since the RG evolution produces non-zero off-diagonal entries in M_R, it has to be re-diagonalized by a unitary transformation, $M_R \to V_R^T M_R V_R = \mathrm{diag}(M_1, M_2, M_3)$, which leads to the rotation, $N_R \to V_R N_R$ and $Y_\nu \to V_R Y_\nu$. Neglecting the corrections proportional to charged-μ and -e Yukawa coupling, y_μ and y_e, we can obtain the RG improved Dirac neutrino Yukawa matrix given for the SM by

$$\widetilde{Y}_\nu(M) \simeq \begin{pmatrix} y_{11} - \epsilon y_{21}\cdot t & y_{12} - \epsilon y_{22}\cdot t & y_{12}^* - (\epsilon y_{22}^* + \frac{3y_\tau^2}{2}y_{12}^*)\cdot t \\ y_{21} + \epsilon y_{11}\cdot t & y_{22} + \epsilon y_{12}\cdot t & y_{22}^* + (\epsilon y_{12}^* - \frac{3y_\tau^2}{2}y_{22}^*)\cdot t \\ 0 & y_{32} & y_{32}^* \end{pmatrix} , \tag{A20}$$

and for the SSM by

$$\widetilde{Y}_\nu(M) \simeq \begin{pmatrix} y_{11} + \frac{2\epsilon}{3}y_{21}\cdot t & y_{12} + \frac{2\epsilon}{3}y_{22}\cdot t & y_{12}^* + (\frac{2\epsilon}{3}y_{22}^* + y_\tau^2 y_{12}^*)\cdot t \\ y_{21} - \frac{2\epsilon}{3}y_{11}\cdot t & y_{22} - \frac{2\epsilon}{3}y_{12}\cdot t & y_{22}^* - (\frac{2\epsilon}{3}y_{12}^* - y_\tau^2 y_{22}^*)\cdot t \\ 0 & y_{32} & y_{32}^* \end{pmatrix} , \tag{A21}$$

where $\cos\alpha = c_\alpha,\;\sin\alpha = s_\alpha$, the components of $\widetilde{Y}_\nu(M)$ are

$$\begin{aligned} y_{11} &\equiv b_3(\lambda c_\alpha + \chi s_\alpha) \;,\;\; y_{12} \equiv b_3(e^{i\phi_2}\kappa s_\alpha + e^{i\phi_1}\omega c_\alpha) \;, \\ y_{21} &\equiv b_3(\chi c_\alpha - \lambda s_\alpha) \;,\;\; y_{22} \equiv b_3(e^{i\phi_2}\kappa c_\alpha - e^{i\phi_1}\omega s_\alpha) \;,\;\; y_{32} \equiv b_3 \;, \end{aligned} \tag{A22}$$

and the parameter ϵ presenting RG corrections is given by

$$\epsilon \simeq \frac{3y_\tau^2\{\frac{\kappa^2-\omega^2}{2}\sin 2\alpha + \kappa\omega\cos 2\alpha\cos\Delta\phi_{12}\}}{\tilde{\delta}} \;. \tag{A23}$$

Note here that the third low of $\widetilde{Y}_\nu(M)$ is not changed because $d(\widetilde{Y}_\nu)_{3k}/dt$ does not depend on A_{12}. As will be shown later, the parameter ϵ is proportional to $y_{\tau\mathrm{SM}}^2$ in the SM and $y_{\tau\mathrm{SM}}^2(1+\tan^2\beta)$ in the SSM and it plays important roles in both leptogenesis and low-energy CP violation. At the seesaw scale, the combination of the Yukawa-Dirac coupling matrices and the mass matrix of right-handed heavy Majorana neutrino, respectively, can be written as

$$\widetilde{H}(M) \equiv \widetilde{Y}_\nu(M)\widetilde{Y}_\nu^\dagger(M) \simeq \begin{pmatrix} \widetilde{H}_{11} & \widetilde{H}_{12} & \widetilde{H}_{13} \\ \widetilde{H}_{21} & \widetilde{H}_{22} & \widetilde{H}_{23} \\ \widetilde{H}_{13} & \widetilde{H}_{23} & H_{33} \end{pmatrix} ,$$
$$M_R \simeq \mathrm{diag}(M_1, M_2, M_3) \ , \quad \text{with } M_2 \lesssim M_1 \ll M_3 \ . \tag{A24}$$

Here the (1,2) and (2,1)-components of $\widetilde{H}(M)$ are the quantities radiatively generated by RG running. Considering the structure of $\widetilde{H}$ in Eq. (A16), up to non-zero leading contributions in the right side of Eq. (A11), the RG equations of $\widetilde{H}_{12}$ are given for the SM by

$$\begin{aligned} \frac{d\mathrm{Re}[\widetilde{H}_{12}]}{dt} &\simeq -3y_\tau^2\mathrm{Re}[(\widetilde{Y}_{\nu1\tau}\widetilde{Y}^*_{\nu2\tau})] + \mathrm{Re}[A_{21}](\widetilde{H}_{22} - \widetilde{H}_{11}) \ , \\ \frac{d\mathrm{Im}[\widetilde{H}_{12}]}{dt} &\simeq -3y_\tau^2\mathrm{Im}[(\widetilde{Y}_{\nu1\tau}\widetilde{Y}^*_{\nu2\tau})] \ , \end{aligned} \tag{A25}$$

and for the SSM by

$$\begin{aligned} \frac{d\mathrm{Re}[\widetilde{H}_{12}]}{dt} &\simeq 2y_\tau^2\mathrm{Re}[(\widetilde{Y}_{\nu1\tau}\widetilde{Y}^*_{\nu2\tau})] + \mathrm{Re}[A_{21}](\widetilde{H}_{22} - \widetilde{H}_{11}) \ , \\ \frac{d\mathrm{Im}[\widetilde{H}_{12}]}{dt} &\simeq 2y_\tau^2\mathrm{Im}[(\widetilde{Y}_{\nu1\tau}\widetilde{Y}^*_{\nu2\tau})] \ . \end{aligned} \tag{A26}$$

Using Eqs. (A9,A18), radiatively generated $\widetilde{H}_{12}$ is given approximately in terms of the parameters in Eqs. (8) and (A16), for the SM, by

$$\begin{aligned} \mathrm{Re}[\widetilde{H}_{12}] &= \mathrm{Re}[\widetilde{H}_{21}] \simeq -\frac{3}{2}y_\tau^2 b_3^2\Big[\frac{1}{2}(\kappa^2 - \omega^2)\sin 2\alpha + \kappa\omega\cos 2\alpha\cos\Delta\phi_{12}\Big]\cdot t \ , \\ \mathrm{Im}[\widetilde{H}_{12}] &= -\mathrm{Im}[\widetilde{H}_{21}] \simeq 3y_\tau^2 b_3^2\omega\kappa\sin\Delta\phi_{12}\cdot t \ , \end{aligned} \tag{A27}$$

and for the SSM by

$$\begin{aligned} \mathrm{Re}[\widetilde{H}_{12}] &= \mathrm{Re}[\widetilde{H}_{21}] \simeq y_\tau^2 b_3^2\Big[\frac{1}{2}(\kappa^2 - \omega^2)\sin 2\alpha + \kappa\omega\cos 2\alpha\cos\Delta\phi_{12}\Big]\cdot t \ , \\ \mathrm{Im}[\widetilde{H}_{12}] &= -\mathrm{Im}[\widetilde{H}_{21}] \simeq -2y_\tau^2 b_3^2\omega\kappa\sin\Delta\phi_{12}\cdot t \ . \end{aligned} \tag{A28}$$

Note here that radiatively generated quantity $\mathrm{Im}[\widetilde{H}_{12}]$ is proportional to $\sin\Delta\phi_{12}$ which is fixed by the angle α in Eq. (A15) due to the $\mu - \tau$ reflection symmetry, and related with low energy observables θ_{13} and J_{CP} in Eqs. (16,19).
